1 Abstract

2 Individual contributions

3 Introduction and Motivations

Everyone is on facebook

Commercials are personalized, the flow of info is interesting for companies

Are there "more important" persons in typical facebook network?

important questions (does the inhomogeneity of the real network influence the "total" evolution? are there "influentials"?)

4 Description of the Model

The process of information spreading has many similarities with epidemiology, so the well known SIR-model was adapted[1]. The "susceptibles", are not aware of the information and are called "ignorants" within this work. "Infected" individuals know about the information and are willing to share it with other people, in other words they spread it and are therefore called "spreaders". The adaptation of the epidemiological term "recovered" is not that straightforward because it is not entirely clear, what that means in this context but they can be looked at persons that are aware of the information but don't want to tell it others. They are called "stiflers".

In the SIR-model as well as in the Agent-based model, the following set of "reaction equations" was used(I: Ignorant, S: Spreader, R: Stifler):

$$\begin{cases} I + S \xrightarrow{\lambda} 2S & (1) \\ S + R \xrightarrow{\alpha} 2R & (2) \\ S + S \xrightarrow{\alpha} S + R & (3) \end{cases}$$

The main difference to the standard SIR-model is that spreaders don't become stiflers spontaneously but this change is only induced by meeting an other spreader or stifler. Also it can be shown that for $\frac{\lambda}{\alpha} > 0$, i.e. for any positive rate, the number of stiflers is non-zero for large times. That means that there is no epidemic threshold as in the standard SIR-model.

Flow Chart of overall steps

Figure 1: Steps performed in each timestep.

4.1 Homogeneous SIR model

In the mathematical treatment of the model in a homogeneous system, the set of differential equations is expressed in terms of the densities $i(t) = I(t)/N$, $s(t) = S(t)/N$ and $r(t) = R(t)/N$.

$$\begin{cases} \frac{di(t)}{dt} = -\lambda \cdot s(t)i(t) & (4) \\ \frac{ds(t)}{dt} = \lambda \cdot s(t)i(t) - \alpha \cdot s(t)[s(t) + r(t)] & (5) \\ \frac{dr(t)}{dt} = \alpha \cdot s(t)[s(t) + r(t)] & (6) \end{cases}$$

4.2 Agent-based model

In the inhomogeneous, agent-based model, the individuals are connected in a certain manner (facebook friends in this particular work). Only connected agents are able to meet. If a meeting occurs, transitions are induced at a certain probability depending on the relation between the agents (details are discussed later). Additional to the different degree of the agents, they also have a different activity, i.e. different probability to meet somebody. In total, the number of meetings in a certain time is proportional to the product of the degree (number of friends) and the activity. This has to be verified in the implementation of the model.

To convert the reaction equations into an agent-based model, time was discretized and in each time step a series of two steps is performed shown in Figure 1. First, the agents randomly meet another agent they know or nobody. Only two-agent meetings are possible. In the second step, the status of the agents change corresponding to the situation. There are six possible combinations of ignorants, spreaders and stiflers. Three of them correspond to the “reactions” 1-3, the other ones (I+I, I+R and R+R) have no other influence than “occupying” the agents. The probability λ was chosen to be dependent on the number of common friends. For simplicity, α was a constant.

5 Implementation

5.1 How did we get our data?

To get the data for our simulation, we used the so-called Facebook Graph API. (reference) What does Graph API mean? A Facebook Graph API is a programming tool designed to support better access to conventions on the Facebook social media platform.¹ It allows you to extract information that is published on facebook, which is exactly what we needed.

Unfortunately, there is no implementation for Matlab, so we programmed the data-fetching in python.

5.2 Coding

5.2.1 Get access

For the coding in python we used the facebook sdk for python².

First, one needs to get access to the social graph. Therefore, you need to enter an access token³.

```
1 token = raw_input('Enter your Access Token: ')
2 anonym = input('Do you want to anonymize your Data? Yes (1) or No (0)? ')
3 graph = facebook.GraphAPI(token)
```

5.2.2 Get graph

Having entered a valid token, we can now access all information this token provides us. For simplicity, we'll only discuss the implementation of the non-anonymized case in details. [For more details on the anonymization, look at subsection anonymization]

```
1 profile = graph.get_object("me")
2 friends = graph.get_connections("me", "friends")
```

In our case, we're interested in data about our own profile, as well as all available information we get from our friends. The object friends is nothing else but an array that contains all id's of our friends, and for each id, there is another array data, that contains all information about this specific friend.

¹<http://www.techopedia.com/definition/28984/facebook-graph-api>

²<https://github.com/pythonforfacebook/facebook-sdk>

³<https://developers.facebook.com/docs/facebook-login/access-tokens/>

```
1 friend_list = [friend['id'] for friend in friends['data']]
```

With this simple for-loop, one can now get a list of all his friends. Since we're not primarily interested in our friends, but the connection in between them, we have to access at least the mutualfriends.

```
1 mutualfriends = graph.get_connections(tfriend, "mutualfriends")
```

The object mutualfriends provides us a list with all mutualfriends of "me" and friend "tfriend" (which is nothing else but one of the id's we have in the saved in "friend_list")

Repeat this procedure for all friends, and we'll get exactly what we're looking for - a graph of all connection of our friends in between of them.

5.2.3 Get activity

5.3 Anonymization

5.4 Homogeneous SIR-model

Urs

5.5 Agent-based model

5.5.1 Initial condition

At the beginning of each simulation, all agents are ignorant but one, which is a spreader. In the simulation,

5.5.2 Determine the meetings

(See `talkstep.m` for details.)

In order to determine who meets who, the program goes through the vector of agents (1:N) randomly. With a probability corresponding to the activity of that agent, he may meet somebody. The person he meets is determined randomly and must be one he knows and one which is not already meeting another agent in this time step. Agents with more friends also have more meetings (If you don't take the activity into account).

5.6 Status changes in meetings

After the meetings are determined, the status of each agent has to change according to the model. In order to be able to determine who infected whom, and how many where infected, a list `infecpath`

6 Simulation Results and Discussion

most important question!

7 Summary and Outlook
